The outcome of a survey of 30 years' experience with heparin treatment in acute thrombo-embolic disease confirms that the absence of any haemorrhagic manifestations at presentation is an important determinant of success. A minimum of at least two of the following signs at presentation are necessary: haemorrhagic tachycardia, haemodynamic instability, haemoptysis and signs of intracranial hypertension. Evidence of recent haemorrhage and recent partial thromboplastin time greater than 1.4 times the control value are the most important determinants of unfavourable outcome. In addition to these, patients with haemorrhagic syndromes which respond poorly to thrombolytic therapy constitute another group which must be treated with heparin therapy. There are few absolute contraindications to anticoagulation and, in the absence of better treatment, heparin is the treatment of choice in these patients. A minimum dosage of heparin must be given and the anticoagulation must be continued for at least 10 days. Since the risk of bleeding is associated with the dose of heparin and the intensity of the thrombotic process, the pharmacologic profile of the drug is of the utmost importance. Heparin produced by standard production methods is best suited for the treatment of thromboembolic disease. In chronic thrombosis treatment with low molecular weight heparin (LMWH) is of increasing importance.
